AMENDMENTS TO THE CLAIMS

1. (Original) A process for the production of chloramine comprising supplying a first reagent stream comprising chlorine gas and a second reagent stream comprising ammonia gas to a reaction zone maintained at a temperature of less than 275°C and configured to allow expansion of the first and second reagent streams in the reaction zone to an extent sufficient to generate chloramine as a gas and ammonium chloride as a free falling solid.

2. (Original) A process according to claim 1 wherein the reaction zone is configured such that at least about 90% of the generated ammonium chloride is formed at least about 10 mm away from any wall of the reaction zone.

3. (Currently amended) A process according to claim 1 ~~or claim 2~~ wherein the reaction zone is bounded towards its top by a reagent supply zone, from which the first and second reagent streams are supplied to the reaction zone.

4. (Currently amended) A process according to claim 3 wherein the reaction zone is bounded towards its bottom by a solids recovery zone, from which solid ammonium chloride ~~may be~~ is recovered, or collected.

5. (Currently amended) A process according to claim 4 wherein the reaction zone is bounded by side walls (or a continuous side wall) extending between the reagent supply zone region and the product recovery zone.

6. (Currently amended) A process according to claim 5 wherein the side wall(s) walls or the continuous side wall bounding the reaction zone circumscribe an expansion region into which gaseous chlorine and ammonia from the reagent streams ~~may expand~~ expand before reacting to form chloramine and ammonium chloride.

7. (Original) A process according to claim 6 wherein the expansion region is configured to provide a laminar flow region for the reaction between chlorine and ammonia to take place.

8. (Currently amended) A process according to claim 6 wherein the expansion region is of a size sufficient to allow at least 60% of the chlorine gas to react before contacting the side wall(s) walls or the continuous side wall.

9. (Currently amended) A process for the production of chloramine comprising:

Appl. No. : Unassigned
Filed : Herewith

providing chlorine gas and ammonia gas to a reaction zone maintained under conditions effective for chlorination of ammonia, and at a temperature of less than 275°C, the reaction zone having a laminar flow region for receiving the chlorine gas and the ammonia gas supplied thereto, whereby chloramine is produced.

10. (Original) A process according to claim 9 wherein the laminar flow region is bounded by a Reynolds Number of not more than 2000.

11. (Currently amended) A chemical reactor suitable for the production of chloramine, the reactor comprising:

a reagent supply zone above a product recovery zone, and with a reaction zone bounded by side walls (or one continuous side wall) extending between the reagent supply zone and the product recovery zone, the reagent supply zone comprising means for supplying, separately, chlorine reagent gas and ammonia reagent gas to the reaction zone, at least one of the supply means being configured to direct a reagent gas into a laminar flow region of the reaction zone.

12. (Currently amended) A reactor according to claim 11 ~~constructed and arranged to operate a process according to any one of claims 1 to 10~~ wherein the reaction zone is configured to be maintained at a temperature of less than 275°C and configured to allow expansion of the reagent gas in the reaction zone to an extent sufficient to generate chloramine as a gas and ammonium chloride as a free falling solid.

13. (New) A reactor according to claim 11, wherein the supply means comprises at least one injection nozzle.
